

Mockup Map Baker

Bake displacement, shadow and highlight maps from a real product photo.

Open a blank mockup shot, pick what the surface is made of, and the panel bakes three greyscale maps from the real photograph — the geometry and lighting that are actually in the image, rather than gradients drawn by hand.

The result is that folds, seams and speculars land where they really are, so artwork composited onto the product sits in the surface instead of on top of it.

DISPLACEMENT

Where the surface bends

Pushes artwork along the slope of each fold, so a logo sinks into a crease instead of floating over it.

SHADOW

How the light falls off

The real lighting across the product, plus the darkening that gathers in every fold valley.

HIGHLIGHT

Where it catches light

Black except the genuine speculars. Matters most on gloss — screens, bottles, vehicle paint.

Five materials, one click

Each preset knows what counts as shape and what counts as lighting on that kind of surface, and sets all nine parameters at once.

Fabric · weave, creases, folds

Paper · gentle bends in the sheet

Screen · panel curvature

Signage · brick and concrete texture

Vehicle · body panels and door seams

THE WHOLE THING

Open the photo → Pick the material → Pick the surface → Generate

The source photo has to be blank.

Artwork already in the shot gets baked in as geometry that isn't there, and no setting can separate a printed logo from a fabric fold — they are the same size on the page.
